MongoDB

The Complete Developer's Guide

Introduction to MongoDB

What is MongoDB?

MongoDB is a database which is created by the company who is also called MongoDB. The name stems from the word "humongous". This database is built to store a lot of data but also being able to work with the huge data efficiently. Ultimately, this is a database solution.

There are many database solutions such as MySQL, PostgreSQL, TSQL etc.

MongoDB is most importantly a database server that allows us to run different databases on it for example a Shop database. Within the database we would have different collections such as a Users collection or a Orders collection. We can have multiple databases and multiple collections per database.

Inside of the collection we have something called documents. Documents look like JavaScript JSON objects. Inside of a collection the documents are schema-less and can contain different data. This is the flexibility that MongoDB provides us with whereas SQL based database are very strict about the data stored within the database tables. Therefore, the MongoDB database can grow with the application needs. MongoDB is a No-SQL database.

Typically we will need some kind of structure in a collection because applications typically requires some type of structure to work with the data.

Diagram 1.1:

JSON (BSON) Data Format:

```
{  
  "name": "Alex",  
  "age": 29,  
  "address": {  
    "city": "Munich"  
  },  
  "hobbies": [  
    { "name": "Cooking" },  
    { "name": "Football" }  
  ]  
}
```

The above is an example of the JSON data format. A single document is surrounded by curly brackets. The data is normally structured with a Keys. Keys consist of a Name of the Key and a Key value. The Name of the Key (*which will be referred to as Key from now on*) and the Key Value must be wrapped around quotation marks (unless if the data is a type of number).

There are different types of values we can store such as: string, number, booleans and arrays.

We can also nest documents within documents. This allows us to create complex relations between

data and store them within one document, which makes working with the data and fetching data more efficient because it is contained in one document in a logical way. SQL in contrast requires more complex method of fetching data which require joins to find data in table A and data in table B to retrieve the relevant data.

Behind the scenes on the server, MongoDB converts the JSON data to a binary version of the data which can be stored and queried more efficiently. We do not need to concern ourselves with BSON as we would tend to work with JSON data.

The whole theme of MongoDB is flexibility, optimisation and usability and it is what really sets MongoDB apart from other database solutions because it is so efficient from a performance perspective as we can query data in the format we need it instead of running complex restructuring on the server.

The Key MongoDB Characteristics.

MongoDB is a no SQL solution because it is following an opposite concept/philosophy to SQL based databases. Instead of normalising the data i.e. storing data distributed across multiple tables where every table has a clear schema and then using relations, MongoDB goes for storing data together in a document. It does not force a schema hence schema-less/No-SQL.

We can have multiple documents in a single collection and they can have different structures as we have seen in Diagram 1.1. This is important, it can lead to messy data but it still our responsibility as developers to work with clean data and to implement a solution that works. On the other hand this provides us with a lot of flexibility. We could use MongoDB for applications that might still evolve, where the exact data requirements are not set yet. MongoDB allows us to started and we could always add data with more information in the same collection at a later point in time.

We also work with less relations. There are some relations, but with these embedded (nested) documents, we have less collections (tables) which we connect but instead we store data together. This is where the efficiencies is derived from, since data is stored together and when we fetch data from our application it does not require to reach out to multiple tables and merge the data because all the data is already within the single collection. This is where the speed, performance and flexibility comes from and can be seen beneficial for when building applications. This is the main reason why No-SQL solutions are so popular for read and write heavy applications.

MongoDB Ecosystem

The below Diagram 1.2 is the current snapshot of the MongoDB companies ecosystem and product offerings. The focus of this guide is on the MongoDB database used locally on our machines and on the cloud using Atlas. We will also dive in Compass and the Stitch world of MongoDB.

Diagram 1.2:

Installing MongoDB

MongoDB runs on all Operating Systems (OS) which include Windows/Mac/Linux. To install MongoDB we can visit their webpage on:

<https://www.mongodb.com/>

Under products select MongoDB server and download the MongoDB Community Server for our OS platform of choice. Install the MongoDB Server by following the installation steps.

Important Note: On Windows when installing click on the Custom Setup Type. MongoDB will be installed as a service which will be slightly different to how MongoDB runs on Mac & Linux.

On Mac and Linux we simply have a extracted folder which contains files. We would copy all the contents within this folder and paste them into any place within our OS i.e wherever we would want to install MongoDB.

We would then want to create a folder called data and a sub-folder called db anywhere within our OS, preferably in the root of the OS.

On Windows open up the command prompt or on Mac/Linux open up the terminal. This is where

we are going to spend most of our time using special commands and queries. Run the following command:

```
$ mongo
```

This should return command not found.

To fix this problem on a Mac go to the user folder and find a file called .bash_profile file (*if this does not exist we could simply create it*). Edit the file using a text editor. Add the following line:

```
export PATH=/Users/Username/mongobd/bin:$PATH
```

The path should be wherever we placed the MongoDB binary zip files. We need to add :\$PATH at the end on Mac/Linux to make sure all our other commands work on our OS. Save the file and close the file.

To fix this on a Windows OS, we need to create an environment variable. Press the windows key and type environment which should suggest the Edit Environment Variable option. Under the user variables edit Path to add the directory path to where we installed the MongoDB files:

```
C:\Program Files\MongoDB\Server\4.0\bin
```

Restart the terminal/command prompt and now run the command:

```
$ mongo
```

This should now return a error of connect failed on Mac/Linux.

On Windows it will connect because MongoDB is running as a service and has already started as a background service because we would have checked this during the installation. If we open the command prompt as administrator and ran the command 'net stop MongoDB' this will stop the background service running automatically and we can manually start and stop the MongoDB service running on windows. DO NOT RUN THIS COMMAND ON MAC/LINUX.

The mongo command is the client which allows us to connect to the server and then run commands on the databases. To start the service on Mac/Linux we would use the following command:

```
$ mongod
```

When running this command to start the server it may fail if we chose a different default /data/db folder. If we used a different folder and not within the root of our OS we would need to start the mongod command instance followed by the --dbpath flag and the place where the /data/db is located if not within the root directory.

```
$ sudo mongod --dbpath "/data/db"
```

On Mac we would need to run the mongod command every time we wish to run the MongoDB service whereas on Windows this will run automatically even after restarting the system.

Now that we have the mongod service running minimise the terminal on Mac/Linux and open up a new terminal. We cannot close the mongod serve terminal because it is running the service and if closed the MongoDB service will stop working and we cannot continue to work with it anymore. Pressing the CTRL + C keys within the terminal will quit the mongod service, but we would need to re-run the mongod command again should we wish to run the service again.

We are now in the mongo shell which is the environment where we can run commands against our database server. We can create new databases, collections and documents which we will now focus on in the following sections.
